(b) acid strength increases from no. 1 to no. 3 or down the table or as Cls increase due to the electron-withdrawing effect/electronegativity of chlorine (atoms) stabilising the anion or weakening the O-H bond NOT $\mathrm{H}^{+}$more available
(ii) chlorine atom is further away (from $\mathrm{O}-\mathrm{H}$ ) in no. 4, so has less influence
(iii) either: $\mathrm{pH}=1 / 2\left(\mathrm{p} K_{\mathrm{a}}-\log _{10}[\right.$ acid $\left.]\right)$ or $K_{\mathrm{a}}=10^{-\mathrm{pKa}}=1.259 \times 10^{-3}$

$\therefore 10.0 \mathrm{~g}$ should give $10 \times 89 / 74=12.03 \mathrm{~g}$

1 mol of ${ }^{12} \mathrm{C}$ has a mass of 12 g
