2 (a any two from: molecules have negligible volume
negligible intermolecular forces or particles are not attracted to each other or to the walls of the container random motion no loss of kinetic energy during collisions or elastic collisions (NOT elastic molecules)
(b) low temperature and high pressure both required [1]
(ii) (at low T ) forces between particles are more important,
(at high P) volume of molecules are significant
(c) endothermic; because the equilibrium moves to the right on heating or with increasing temperature or because bonds are broken during the reaction
(ii) e.g. halogenation or Friedel-Crafts alkylation/acylation

other possibilities: $\mathrm{Cl}_{2}, \mathrm{I}_{2}, \mathrm{R}-\mathrm{Cl}, \mathrm{RCOCl}$ etc.

(b) Because each carbon is only bonded to 3 others or is unsaturated/doubly-bonded/ $\mathrm{sp}^{2}$ or has 3 bonding locations
(NOT forms only 3 bonds)

(c) Number of atoms carbon present $=0.001 \times 6.02 \times 10^{23} / 12=5.02 \times 10^{19}$

Area of sheet $=690 \times 2.51 \times 10^{19}=1.73 \times \mathbf{1 0}^{22} \mathbf{n m}^{2}$
(iii) Graphene: Yes, since it has free/delocalised/mobile electrons

Buckminsterfullerene: No, (although there is delocalisation within each sphere) it consists of separate/simple/discrete molecules/spheres/particles, (so no delocalisation from one sphere to the next)
or electrons are trapped within each molecule/sphere
